Contents

General Notes

All in `Python3`.

0 Day 0: Hello, World.

```python
# Read a full line of input from stdin and save it to our
    dynamically typed variable, input_string.
inputString = input()
print (inputString)
```

1 Day 1: Data Types

```python
i = 4
d = 4.0
s = 'HackerRank '

# Declare second integer, double, and String variables.
i2 = int(input())    # read int
d2 = float(input()) # read double
s2 = input()         # read string

# print summed and concatenated values
print(i + i2)
print(d + d2)
print(s + s2)
```

2 Day 2: Operators

```python
mealCost   = float(input())
tipPercent = int(input())
taxPercent = int(input())

tip = mealCost * (tipPercent/100.)
tax = mealCost * (taxPercent/100.)

totalCost = mealCost + tip + tax
total = round(totalCost)

print ('The total meal cost is', int(total), 'dollars.')
```

3 Day 3: Intro to Conditional Statements

```python
import sys

N = int(input().strip())
condition = 'Not Weird'

if N % 2 != 0:
    condition = 'Weird'
elif N % 2 == 0 and (N >= 6 and N <= 20):
    condition = 'Weird'
else:
    condition = 'Not Weird'

print(condition)
```

4 Day 4: Class vs. Instance

```
'''
Objective:

In this challenge, we are going to learn about the difference
    between a class and an instance; because this is an Object
    Oriented concept, it is only enabled in certain languages.
    Check out the Tutorial tab for learning materials and an
    instructional video!

Task:
Write a Person class with an instance variable, age, and a
    constructor that takes an integer, initialAge, as a parameter.
    The constructor must assign initialAge to age after confirming
    the argument passed as initialAge is not negative; if a
    negative argument is passed as initialAge, the constructor
    should set age to 0 and print Age is not valid, setting age to
    0. In addition, you must write the following instance methods:

yearPasses() should increase the age instance variable by 1.

amIOld() should perform the following conditional actions:
   If age< 13 , print You are young.
   If >= 13 and age < 18, print You are a teenager.
   Otherwise, print You are old.

To help you learn by example and complete this challenge, much of
    the code is provided for you, but you''ll be writing everything
    in the future. The code that creates each instance of your
    Person class is in the main method. Dont worry if you dont
    understand it all quite yet!
'''

class Person:
    def __init__(self,initialAge):
        # Add some more code to run some checks on initialAge
        self.age = 0
        if initialAge < 0:
            print ("Age is not valid, setting age to 0.")
        else:
            self.age = initialAge

    def amIOld(self):
        # Do some computations in here and print out the correct
            statement to the console
        if age < 13:
            print("You are young.")
        elif 13 <= age < 18:
```

```python
            print("You are a teenager.")
        elif age >= 18:
            print("You are old.")

    def yearPasses(self):
        # Increment the age of the person in here
        global age  #NPR: don't quite undesrstand what global does
            here...
        age += 1

t = int(input())
for i in range(0, t):
    age = int(input())
    p = Person(age)
    p.amIOld()
    for j in range(0, 3):
        p.yearPasses()
    p.amIOld()
    print("")
```

5   Day 5: Loops

```
'''
Objective:
In this challenge, we are going to use loops to help us do some
    simple math. Check out the Tutorial tab to learn more.

Task
Given an integer, , print its first multiples. Each multiple (where
    ) should be printed on a new line in the form: N x i = result.
'''
import sys

N = int(input().strip())

for ii in range(1, 11):
    print (N,'x', ii ,'=', N*ii)
```

6 Day 6: Let's Review

Task:
Given a string, S, of length N that is indexed from 0 to N-1, print
    its even-indexed and odd-indexed characters as space-separated
    strings on a single line (see the Sample below for more detail).

Note: 0 is considered to be an even index.

Sample Input:
2
Hacker
Rank

Sample Output:
Hce akr
Rn ak
'''

```python
for i in range(int(eval(input()))):
    s=eval(input())
    print((*["".join(s[::2]),"".join(s[1::2])]))
```

7 Day 7: Arrays

```
'''
Task: Given an array, A, of N integers, print A''s elements in
    reverse order as a single line of space-separated numbers.

http://docs.scipy.org/doc/numpy/reference/routines.array-manipulation.html
http://www.scipy-lectures.org/intro/numpy/numpy.html
'''

import sys

n = int(input().strip())
arr = [int(arr_temp) for arr_temp in input().strip().split(' ')]

# print(arr[::-1])
print(" ".join(map(str, arr[::-1])))
```

8 Day 8: Dictionaries and Maps

```
'''
Objective:: Today, we are learning about Key-Value pair mappings
    using a Map or Dictionary data structure. Check out the
    Tutorial tab for learning materials and an instructional video!

Task:: Given N names and phone numbers, assemble a phone book that
    maps friends names to their respective phone numbers. You will
    then be given an unknown number of names to query your phone
    book for; for each name queried, print the associated entry
    from your phone book (in the form ) or if there is no entry for
    .

Note: Your phone book should be a Dictionary/Map/HashMap data
    structure.

Sample Input:
3
sam 99912222
tom 11122222
harry 12299933
sam
edward
harry
'''

import sys

# Read input and assemble phoneBook
n = int(input())
phoneBook = {}
for i in range(n):
    contact = input().split(' ')
    phoneBook[contact[0]] = contact[1]

# Process Queries
lines = sys.stdin.readlines()
for i in lines:
    name = i.strip()
    if name in phoneBook:
        print(name + '=' + str( phoneBook[name] ))
    else:
        print('Not found')
```

9   Day 9: Recursion

```
'''
Objective:: Today, we are learning and practicing an algorithmic
    concept called Recursion. Check out the Tutorial tab for
    learning materials and an instructional video!

Task:: Write a factorial function that takes a positive integer, N,
    as a parameter and prints the result of N!

Note: If you fail to use recursion or fail to name your recursive
    function factorial or Factorial, you will get a score of 0.

Input Format: A single integer, N (the argument to pass to
    factorial).

'''

def factorial(n):
    if n == 0 or n == 1:
        return 1
    else:
        return n * factorial(n-1)

print((factorial(int(eval(input())))))
```

10 Day 10: Binary Numbers

```
'''
Task:: Given a base-10 integer, n, convert it to binary (base-2).
    Then find and print the base-1- integer denoting the maximum
    number of consecutive 1''s in n''s binary representation.

'''

bin(11111113)
# '0b101010011000101011001001'

bin(11111113)[2:]
# '101010011000101011001001'

bin(11111113)[2:].split()
# ['101010011000101011001001']

bin(11111113)[2:].split('0')
# ['1', '1', '1', '', '11', '', '', '1', '1', '11', '', '1', '',
    '1']

max(bin(11111113)[2:].split('0'))
# '11'

#len(max(bin(11111113)[2:].split('0')))

print(len(max(bin(int(input().strip()))[2:].split('0'))))
```

11 Day 11: 2D Arrays

```
'''
Context: Given a 6x6 2D Array, A:

1 1 1 0 0 0
0 1 0 0 0 0
1 1 1 0 0 0
0 0 0 0 0 0
0 0 0 0 0 0
0 0 0 0 0 0

We define an hourglass in A to be a subset of values with indices
    falling in this pattern in As graphical representation:

a b c
  d
e f g

There are 16 hourglasses in A, and an hourglass sum is the sum of
    an hourglass'' values.

Task:: Calculate the hourglass sum for every hourglass in A, then
    print the maximum hourglass sum.

Sample Input::
1 1 1 0 0 0
0 1 0 0 0 0
1 1 1 0 0 0
0 0 2 4 4 0
0 0 0 2 0 0
0 0 1 2 4 0

Sample Output::
19
'''

import sys

arr = []
for arr_i in range(6):
    arr_t = [int(arr_temp) for arr_temp in input().strip().split('
        ')]
    arr.append(arr_t)

res = []
for x in range(0, 4):
    for y in range(0, 4):
        print(x,y)
```

```python
        print('arr[x][y:y+3]', arr[x][y:y+3])
        print('arr[x+1][y+1]', arr[x+1][y+1])
        print('arr[x+2][y:y+3]', arr[x+2][y:y+3])
        s = sum(arr[x][y:y+3]) + arr[x+1][y+1] + sum(arr[x+2][y:y+3])
        res.append(s)

print(max(res))
```

12   Day 12: Inheritance

```
'''
Objective:: Today, we are delving into Inheritance. Check out the
    Tutorial tab for learning materials and an instructional video!

Task:: You are given two classes, Person and Student, where Person
    is the base class and Student is the derived class. Completed
    code for Person and a declaration for Student are provided for
    you in the editor. Observe that Student inherits all the
    properties of Person.

Complete the Student class by writing the following:
A Student class constructor, which has parameters:
A string, firstName.
A string, lastName.
An integer, id.
An integer array (or vector) of test scores, scores.

A char calculate() method that calculates a Student object''s
    average and returns the grade character representative of their
    calculated average.

Sample Input::
Heraldo Memelli 8135627
2
100 80

Sample Output::

 Name: Memelli, Heraldo
 ID: 8135627
 Grade: O

'''

class Person:
    def __init__(self, firstName, lastName, idNumber):
        self.firstName = firstName
  self.lastName = lastName
  self.idNumber = idNumber
    def printPerson(self):
        print("Name:", self.lastName + ",", self.firstName)
        print("ID:", self.idNumber)

class Student(Person):
    def __init__(self, firstName, lastName, idNumber, scores):
        Person.__init__(self, firstName, lastName, idNumber)
```

```python
        self.testScores = scores

    def calculate(self):
        average = 0
        for i in self.testScores:
            average += i

        average = average / len(self.testScores)

        if(average >= 90):
            return 'O' # Outstanding
        elif(average >= 80):
            return 'E' # Exceeds Expectations
        elif(average >= 70):
            return 'A' # Acceptable
        elif(average >= 55):
            return 'P' # Poor
        elif(average >= 40):
            return 'D' # Dreadful
        else:
            return 'T' # Troll

line = input().split()
firstName = line[0]
lastName = line[1]
idNum = line[2]
numScores = int(input()) # not needed for Python
scores = list( map(int, input().split()) )
s = Student(firstName, lastName, idNum, scores)
s.printPerson()
print("Grade:", s.calculate())
```

13 Day 13: Abstract Classes

```
'''
Objective:: Today, we are taking what we learned yesterday about
    Inheritance and extending it to Abstract Classes. Because this
    is a very specific Object-Oriented concept, submissions are
    limited to the few languages that use this construct. Check out
    the Tutorial tab for learning materials and an instructional
    video!

Task:: Given a Book class and a Solution class, write a MyBook
    class that does the following:
-- Inherits from Book

-- Has a parameterized constructor taking these parameters:
   -- string title
   -- string author
   -- int price

Implements the Book class abstract display() method so it prints
    these 3 lines:
 1. Title, a space, and then the current instances title.
 2. Author, a space, and then the current instances author.
 3. Price, a space, and then the current instances price.

Note: Because these classes are being written in the same file, you
must not use an access modifier (e.g.: ) when declaring MyBook or
    your
code will not execute.

Input Format:: You are not responsible for reading any input from
    stdin. The Solution class creates a Book object and calls the
    MyBook class constructor (passing it the necessary arguments).
    It then calls the display method on the Book object.

Output Format:: The void display() method should print and label
    the respective, title, author and price of the MyBook objects
    instance (with each value on its own line) like so:
Title:    $title
Author: $author
Price:    $price
Note: The is prepended to variable names to indicate they are
    placeholders for variables.

Sample Input::
The following input from stdin is handled by the locked stub code
    in your editor:
The Alchemist
Paulo Coelho
```

```python
from abc import ABCMeta, abstractmethod

class Book(object, metaclass=ABCMeta):
    def __init__(self,title,author):
        self.title=title
        self.author=author
    @abstractmethod
    def display(): pass

class MyBook(Book):
    price = 0
    def __init__(self, title, author, price):
        super(Book, self).__init__()
        self.price = price

    def display(self):
        print("Title: "+ title)
        print("Author: "+ author)
        print("Price: "+ str(price))

title   =input()
author  =input()
price   =int(input())
new_novel=MyBook(title,author,price)
new_novel.display()
```

14 Day 14: Scope

15 Day 15: Linked List

16 Day 16: Exceptions - String to Integer

17 Day 17: More Exceptions

18 Day 18: Queues and Stacks

19 Day 19: Interfaces

20 Day 20: Sorting

21 Day 21: Generics

22 Day 22: Binary Search Trees

23 Day 23: BST Level-Order Traversal

24 Day 24: More Linked Lists

25 Day 25: Running Time and Complexity

26 Day 26: Nested Logic

27 Day 27: Testing

28 Day 28: RegEx, Patterns, and Intro to Databases

29 Day 29: Bitwise AND
